Anatomy of a Coaxial Connector

There are a wide variety of coaxial connectors available today. These connectors are offered in numerous interface types and attachment methods. Illustrated below are some common elements and functions shared by most of these coaxial connectors.

Attachment sleeve to cable outer conductor.

Coupling Body

Attachment mechanism to mating connector.

Outer Conductor

Outer conducting element for signal transmission.

Dielectric Support

Non-conductive spacer between center and outer conductor.

Center Conductor

Center conducting element for signal transmission.

Building Your Own Coaxial Cable Assembly

In order to successfully build your own coaxial cable assembly, you must make the following decisions:

1. Select a cable type

Many parameters come into play in making this decision from electrical performance properties such as impedance, shielding and attenuation to mechanical properties such as diameter, center conductor construction (solid vs stranded) and jacket material. A selection of the most commonly used cable is listed on page 147.

2. Select a connector type

Numerous connector interfaces exist such as BNC, TNC, SMA, F or RCA

to name just a few. Each has a different application and come in both male and female versions. A selection of the most popular types is listed on pages 148-150 and 158-159.

3. Select an attachment method

In general, there are three basic methods to attach a coaxial connector to a coaxial cable. They are crimp, clamp and twist-on. Each of these methods is illustrated below.

If a crimp attachment method was selected then a crimp tool will be needed. The crimp cross reference chart on page 151 will assist you in selecting the correct tool.

Crimp Method: This is the most common connector attachment method. In this case the cable shield is crimped to the connector using the crimp ring. The connector center conductor is attached to the cable center conductor by crimp or solder.

Cut cable to length and slide crimp ring onto free end.

Strip free end with Coaxial

Slide pin onto center conductor Fan braid and slide plug over making sure base of pin meets pin dielectric. Crimp in place.

Pull crimp sleeve over braid

Crimp in place.

Clamp Method: The clamp method is often used for weather exposure applications or when crimp tools are not available. In this case the cable shield is clamped between the connector body and back nut. The connector center conductor is usually soldered to the cable center conductor.

Cut cable and slide nut into position. Strip and flair braid.

Position braid clamp and crimp Attach main body to back nut.

Twist-On Method: This method is most often used in field applications because of it's simplicity and the need for no special tools.

Prepare cable with strip tool.

Position connector body

Twist connector body onto cable

Crimp Tool:

When using a crimp connector, the HT330K tool kit can be a valuable item (page 151). This kit contains dies for all the commonly used crimp sizes. In addition, this kit comes complete with a cable cutter and a rotary cable stripper - helpful tools for building a cable assembly.

Plug or Jack:

A PLUG utilizes a center pin = MALE GËNDER

A JACK utilizes a center socket = FEMALE GENDER

Solid or Stranded:

SOLID center conductor: best attenuation but somewhat stiff.

STRANDED center conductor: more flexible but slightly higher attenuation.

"L-com's site is one of the best sites. A lot of manufacturers make it impossible to find drawings or data sheets on their sites, but yours are always right there. Being able to get pricing and check stock online is another time saver." - James Hopkins, Debcor Industries
